

ASD Longitudinal RMD

Stan West

2025-04-17

This Markdown summarizes information regarding the data that will be used for a longitudinal analysis of vocabulary acquisition in autistic children. Here we are interested in vocabulary sizes between 3 & 600 words produced. The numbers reported here differ from our first look because of a couple of reasons:

1. I recycled old code from a different project to combine the old and new GUIDs. This code had a part where we were only accepting the “best” CDI record (that with the highest number of words produced across multiple records). This was reducing the number of possible longitudinal data points. Good news, we have more kids with longitudinal data 9 - 15 months between CDIs.
2. I used an “|” instead of “&” when defining the 2 - 4 window for kids with more granular longitudinal data. This made it seem like we had much more kids with fine-tuned longitudinal data. After fixing this, we only have 6 kids with data at that level of specificity.

Demographic Information

Demographics for kids with between 3 & 600 productive vocabulary. The majority of kids have early interviews with relatively low productive vocabularies.

Longitudinal Analysis - all kids (no restriction on time between CDIs)

Of the 628 CDIs, 206 only have an entry for a single age, removing them from longitudinal consideration. That leaves 422(111 unique kids) with at least 2 CDIs.

Table 1: CDI Longitudinal Counts

# of CDIs	# of Records	# of Kids
1	207	207
2	102	51
3	162	54
4	128	32
5	30	6

Kids with longitudinal data in 3 month intervals

There are only 6 kids with between 2 and 4 months between CDIs. This is different from our first look at this because we mistakenly used “|” in our filter instead of “&” when defining our time window. There are 9 total records with between 2 and 4 months in between CDIs, with the majority of those (4) being 4 months apart.

Many of the kids with more frequent CDIs (2 - 4 months apart) have several CDI administrations, however, for most of the kids only 2 timepoints will work for this analysis (e.g., “NDARET878JC0” has 5 CDIs, but only vocabularies at 57 and 60 months would be applicable).

Kids with longitudinal data in 9 - 15 month intervals

There are 111 kids with CDIs at the specificity of 9 - 15 months between CDIs. Below are tables and figures showing the distribution of time between CDIs both across participants and how many individual participants have multiple CDIs within the 9 - 15 time range. The majority of CDIs that meet the 9 - 15 month criteria fall in the 12-month time between CDIs. Additionally, the majority (79 of 111) only have one instance of records that are 9 - 15 months apart.

[1] “There are 111 unique kids with CDIs 9 - 15 months between CDIs” [1] “There are 150 cases of CDIs being between 9 and 15 months apart. The counts are shown below.”

Table 3: CDI Latencies Counts

Month Latency	Count
9	8
10	14
11	19
12	52
13	28
14	15
15	14

Table 4: Multiple Contributions Counts: Note: 1 contribution = 2 CDIs 9-15 months apart

# of Contributions	Count
1	79
2	25
3	7

Histograms

Graphical representation of tables above. Plot on the bottom: red lines reflect the 9 - 15 month cutoffs. If we want to focus on a single time interval between CDIs, we will retain the most data for 12 months between administrations.

Distributions of first interviews

Histograms show the ages of first administration for kids with longitudinal data between 9 and 15 months apart. The second plot facets this by the number of longitudinal data points available.

Distribution of First Interviews

Distribution of First Interviews

Spaghetti Plots

Plots showing the progression of productive vocabulary over interview age. The majority of kids show increases in productive vocabulary over time, but this is not always the case. Page 10 digs deeper into those cases.

Red connections are 9-15 month gaps between CDIs

Inconsistent gains in vocabulary over time

Some of the kids show drops in vocabulary size between CDI administrations. There are 30 kids who have longitudinal CDIs that decrease at some point in development. These may be considerations for removal as they do not follow the pattern of development of the majority of the kids. It is impossible to know if this is due to bad reporting or legitimate losses in productive vocabulary (Arunachalam, S., Avtushka, V., Luyster, R. J., & Guthrie, W. (2022). Consistency and inconsistency in caregiver reporting of vocabulary. *Language Learning and Development*, 18(1), 81-96. <https://pmc.ncbi.nlm.nih.gov/articles/PMC9119658/pdf/nihms-1714234.pdf>).

Mean Vocabulary Decreases	SD	Range
-37.13158	43.35409	-241
-37.13158	43.35409	-1

Top 40 words not consistently reported across CDIs.

This is data aggregated across kids with longitudinal data with 9 - 15 months between CDIs where the vocabulary size decreased with age

Here, we are looking at item-level distributions of the top 40 words that were reported as being known in the first CDI administration, but not reported as being known in at least one of the subsequent administrations. The bars are filled by CDI category. Values on the x-axis report the number of times the word was reported on the first administration of the CDI but not later CDIs.

Overall distribution of omissions across categories

The majority of words not being included in subsequent CDIs are action words, followed by animals and food and drinks.

Skips 12 months apart for more than 2 CDIs

Some kids have CDIs that are around 12 months apart between two administrations, but there is a larger gap in subsequent administrations. We can make predictions about the vocabulary size in these gaps using linear models. Below are some examples of kids with 12 month administrations and larger gaps in times between CDIs. Some kids start with more frequent CDIs and they become less frequent over time (e.g., NDARAJ572PGT) and some start with less frequent CDIs and progressively get more frequent (NDAREH113WHB).
